HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L'archive ouverte pluridisciplinaire **HAL**, est destin ee au d ep ot et  a la diffusion de documents scientifiques de niveau recherche, publi es ou non,  emanant des  tablissements d'enseignement et de recherche fran ais ou  trangers, des laboratoires publics ou priv es.

Active and Visually-guided Navigation in Virtual Reality (VR) Benefit Route Memory

- Spatial memory is enhanced when encoding is active rather than passive¹
- Active encoding consists of physical movement and cognitive components such as attention, mental manipulation of maps, and decision-making²
- Recent findings suggests that spatial memory suffers when we rely on an AI device^{3,4}, like a GPS, to make decisions about our path of travel

We compared memory for spatial routes, encoded using navigation strategies that differentially engaged decision-making about the path of travel

Procedure: Participants ($n=50$) explored 12 VR maps for 40 secs each. Encoding was either done Passively (observed a video), using visual guidance similar to GPS, or Actively (making own decisions about where to turn). Maps were created using MapBox, and were based on real-world map layouts of cities (e.g., Tokyo, Manhattan).

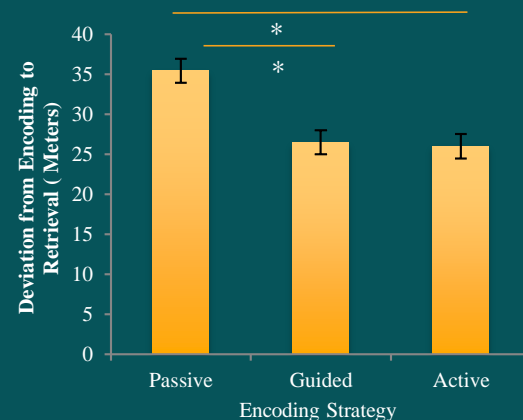

Encoding

Passive: Watched a 360 video in VR of someone else's travel to gold-star – did not initiate movement

Guided: Followed a visual cue to the gold-star

Active: Decided the path of travel to find gold-star

Retrieval: Participants re-entered each map, and “re-traced” the exact route they had travelled, for 40 secs each.

DISCUSSION

- Active and Guided navigation led to less deviation in memory for the route travelled, from encoding to retrieval, **suggesting better memory when movements during exploration are self-generated**
- Critically, **time stopped at intersections** ($B = -5.13, p = .010$) and the number of **intersections** ($B = -1.87, p = .007$) **traversed**, predicted performance following Active encoding only
- Removing decision-making during visually Guided navigation did not negatively impact route memory
